Role

Lead Generation & Competitor Analysis

Tech Stack

FastAPI Python Web scraping (page fetch + extraction) Google Places-style
business lookup SQLite

1. Lead Generation

- Built the **Lead Intelligence** flow: given filters (brand, country, industry), discovers and scores prospects.
- Every lead gets a transparent **5-factor fit score**: Industry Fit, Company Profile, Geo Relevance, Product Fit, Insurance Need — each factor has its own reasoning shown on expand, not just a total number.
- Leads are tagged by source honesty:
 - `VERIFIED SOURCE` — real, independently-confirmed business (real address, sometimes a real discovered contact email).
 - `AI-GENERATED PROSPECT` — a plausible AI-invented profile, used only when real lead-sourcing isn't configured.
- Built the **Enrich** step: pastes a company's real website URL and pulls a verified description + contact email from that live page — never invents a phone/email that wasn't actually found.

How it works: filters → discovery call → each candidate scored on the 5 factors → tagged VERIFIED/AI-GENERATED → optional enrichment against the company's real site → feeds into outreach draft generation (compliance gate still applies to outreach emails before they can be sent).

2. Competitor Analysis

- Built the **Competitor Intelligence** flow: given a competitor's real URL and a brand it's relevant to, performs a real, safe fetch and extracts title/description/headings.
- Built the **Competitor Change Digest**: compares a competitor's two most recent snapshots and reports exactly what changed — a factual diff, not a generated guess.
- Built **Snapshot History** per competitor, so every past research pass is kept on file.

How it works: URL submitted → page scraped/extracted → stored as a dated snapshot → next run on the same competitor is diffed against the prior snapshot to surface real, dated changes.

Notes

Fill in the specific scraping library used (e.g. Playwright, Crawl4AI, ScrapeGraphAI, requests+BeautifulSoup) and file paths (e.g. `lead_agent.py`, `competitor_agent.py`) before committing to GitHub.
